

Antarctic Meteorite NEWSLETTER

A periodical issued by the Antarctic Meteorite Working Group to inform scientists of the basic characteristics of specimens recovered in the Antarctic.

Volume 6, Number 1

February, 1983

Supported by the National Science Foundation, Division of Polar Programs, and compiled at Code SN2, Johnson Space Center, NASA, Houston, Texas 77058

SAMPLE REQUESTS and ALLOCATIONS

The Meteorite Working Group will meet from April 14-17, 1983, for the purpose of reviewing requests for Antarctic Meteorites.

Requests for specific samples (including sample name/number, weight requested, a brief description of the intended meteorite investigation, and pertinent sample specifics) should be sent to:

Secretary, MWG Planetary Materials Branch, SN2 NASA, Johnson Space Center Houston, TX 77058

HIGHLIGHTS OF THE 1982-83 FIELD SEASON

- A major new area of meteorite concentration has been discovered only 325 miles from the South Geographic Pole at the Pecora Escarpment. A reconnaissance team, traveling by snow mobile and sledge, visited the site during late December and January and established the existence of the meteorite concentration but was unable to examine more than a small fraction of the total area of exposed ice. The potential for large-scale future recovery here is considered excellent.
- 2. Important new concentrations of meteorites were identified by the same team at Davies and Moulton Escarpments in the vicinity of the Thiel Mountains.
- Another field team established the occurrence of meteorites at the Allan Hills Far Western Ice Field. This was a surprise because during a brief visit some years earlier, none had been found; therefore this very large area of exposed ice had been considered barren of meteorites.
- 4. This field team also revisited Elephant Moraine and made reconnaissance searches which greatly enlarge the known areas of meteorite occurrence in that region.
- 5. A chondrite was found apparently weathering out of the ice at the Far Western Ice Field. This specimen was collected in situ in a large block of encasing ice.
- 6. Total meteorite recoveries for both teams were as follows:

3 carbonaceous chondrites 7 achondrites 3 chondrites

103 chondrites

113 Total

This is smaller than in other years, but is considered satisfactory in view of the primarily reconnaissance nature of the total effort this year.

7. Progress was made in extending the Allan Hills triangulation chain further to the west.

ANTARCTIC METEORITES - NEW CLASSIFICATIONS

| NAME | WEIGHT | CLASSIFICATION | WEATHERING | FRACTURING | PAGE |

Sample No.: ALHA81001 Location: Allan Hills

Field No.: 1505 Weight (gms): 52.9

Meteorite Type: Eucrite (anomolous)

Physical Description: Roberta Score

This achondrite is covered on two surfaces with a shiny black fusion crust. The interior appears massive and is a smokey gray color. Many cracks penetrate the interior of this meteorite. After drying in a nitrogen cabinet for several hours, a minute amount of white deposit lines one crack.

Dimensions: $4.5 \times 4.0 \times 4.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section is translucent in pale brown-gray, with some darker areas, giving a patchy appearance. With crossed polars the material is seen to consist of pyroxene prisms up to 0.5 mm long, mostly with straight extinction, in a glassy groundmass. No opaque minerals are present. Microprobe analyses show the pyroxene has rather uniform composition, averaging Wo $_{1.6}$ En $_{40}$ Fs $_{59}$, with 0.4% Al $_{20}$, 0.2% TiO $_{2}$, 0.9% MnO, and 0.6% Cr $_{20}$. Broad-beam analyses give an approximate bulk composition (weight percent) as follows: SiO $_{2}$ 49, Al $_{20}$ 14, FeO 18, MgO 6.7, CaO 10, Na $_{20}$ 0.2, K $_{20}$ <0.1, TiO $_{2}$ 0.9, Cr $_{20}$ 0.6, MnO 0.7. This composition agrees with that of an average eucrite, except that Na $_{20}$ is lower (in most eucrites Na $_{20}$ is about 0.5%); however, the texture is quite different from any described eucrite. The overall impression from the texture is that the material represents a rapidly quenched melt.

Sample No.: ALHA81002 Location: Allan Hills

Field No.: 1591 Weight (gms): 14.0

Meteorite Type: C2 Carbonaceous Chondrite

Physical Description: Roberta Score

No fusion crust remains on this friable, jet black colored carbonaceous chondrite. The overall shape is pyramidal. Rounded inclusions which show relief from the surface are visible on the exterior. A minute amount of white deposit is present on one surface.

The interior contains a few small (<1 mm) white irregular shaped inclusions plus several chondrules and irregular shaped black inclusions.

Dimensions: $2.5 \times 2.5 \times 2.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows numerous small colorless grains (up to 0.1 mm) and irregular aggregates (up to 0.3 mm), mainly of olivine, and a few small chondrules (up to 0.6 mm), in an opaque to translucent matrix. Trace amounts of metal and troilite are present as widely dispersed minute grains. Microprobe analyses of the olivine show a wide composition range: Fa 0-52, mean Fa 11, with a strong peak at Fa 0-1, characteristic for the chondrule olivine; isolated olivine grains show a wide range in composition. A few grains of clinoenstatite (Fs 0-2) and one grain of diopside were analyzed. The meteorite is a C2 chondrite.

Sample No.: ALHA81003 Location: Allan Hills

Field No.: 1228 Weight (gms): 10.1

Meteorite Type: C3V Carbonaceous Chondrite

Physical Description: Roberta Score

One small patch of fusion crust remains on this clastic carbonaceous chondrite. Abundant irregular shaped white inclusions dot the otherwise black surface. Few of the inclusions are oxidated. Metal was noted.

Dimensions: $2.5 \times 2.0 \times 1.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows numerous chondrules up to 3 mm across and irregular crystalline aggregates up to 2 mm in maximum dimension set in a minor amount of dark brown to black semi-opaque matrix. The chondrules and aggregates consist mainly of olivine with some polysynthetically twinned pyroxene. Trace amounts of nickel-iron are present as minute grains. Sulfide is present in minor amount, finely dispersed throughout the section. Microprobe analyses of chondrule's olivine show a wide composition range: Fa 0-40, mean Fa 8; the matrix consists largely of fine-grained iron-rich olivine, Fa 40-60. Pyroxene in the chondrules is clinoenstatite, mostly near Fs 1, but with occasional Fe-rich grains. The meteorite is classified as a C3V chondrite.

Sample No.: ALHA81004 Location: Allan Hills

Field No.: 1429 Weight (gms): 4.7

Meteorite Type: C2 Carbonaceous Chondrite

Physical Description: Roberta Score

Dull black fusion crust covers most of this carbonaceous chondrite. Along one edge the fusion crust has a blistery texture. Small white irregular and rounded inclusions are visible in the black matrix. Several small oxidation haloes were noted.

Dimensions: $3.0 \times 1.5 \times 1.0 \text{ cm}$.

Petrographic Description: Brian Mason

This section is similar to that of ALHA81002 in all respects, and the range and distribution of olivine compositions is the same. It is therefore tentatively paired with that meteorite, and also with ALHA77306 and ALHA78261, previously described C2 chondrites from the Allan Hills.

Sample No.:

ALHA81005

Location: Allan Hills

Field No.:

1422 31.4

Weight (gms): Meteorite Type:

Anorthositic Breccia

Physical Description: Roberta Score

This is an unusual looking sample! Flow marks are apparent on the exterior which is covered with a pitted, glassy, greenish-tan colored crust. Immediately underneath this crust, the surface is a "dusty" gray color.

The interior consists of abundant angular clasts, which range in color from gray to white, set in a black matrix. The size of the clasts are as small as submillimeter and as large as 8 mm in diameter. The sample is very coherent. Some areas of oxidation were noted.

Dimensions: $3 \times 2.5 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

The specimen is a microbreccia of clasts (maximum dimension 4 mm) in a translucent to semi-opaque dark brown glassy matrix showing flow structure in places; clast:matrix ratio is approximately 40:60. The larger clasts are polymineralic, the smaller (less than 0.3 mm) may be individual mineral grains. The clasts consist largely of plagioclase, together with some pyroxene and occasional olivine; most of the mineral grains are plagioclase. The clasts show a variety of textures, including gabbroic, diabasic, and basaltic; many have been shocked and partly granulated. Some of the clasts resemble eucrites, but many appear to be more feldspathic than most eucrites. The section is notable for the complete absence of opaque minerals, except for a 1 mm metal grain. Microprobe analyses show that the plagioclase is very Ca-rich, averaging An 97 (range An 95-98); pyroxene is variable in composition, Wo 1-41, En 44-79, Fs 7-47 (richer in En than most eucrite pyroxenes); several grains of olivine, Fa 11-40, were analyzed. The meteorite is a breccia, but more feldspathic than most eucrites; some of the clasts resemble the anorthositic clasts described from lunar rocks.

ALHA81006

Field No.:

1549

Weight (gms):

254.9

Meteorite Type:

Polymict Eucrite

Physical Description: Roberta Score

Shiny black fusion crust covers all but one fracture surface, though the fracture surface has millimeter sized patches of fusion crust on it.

ALHA81006 looks typical of the other Allan Hills polymict eucrites. Two notable large clasts are: a fine-grained black clast that is 7×11 mm in diameter and a yellow eucritic clast which is covered with fusion crust, that is 15×13 mm in diameter. The latter clast can easily be plucked from the surface.

Dimensions: $11 \times 4.5 \times 3.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows a breccia of angular fragments of pigeonite and plagioclase up to 2 mm across, and some lithic clasts up to 3 mm across, in a matrix of comminuted pyroxene and plagioclase. The lithic clasts consist of pyroxene and plagioclase and range in texture from fine-grained basaltic to coarse-grained gabbroic. A little limonitic staining is present in the lithic clasts. Microprobe analyses show pigeonite with a wide range of composition: Wo 1-15, En 34-59, Fs 35-60, with Al₂O₃ 0.3-2.2%, Cr₂O₃ 0.2-1.5%, TiO₂ 0.2-0.4%. Plagioclase ranges in composition from An 84-94 with a mean of An 89. The meteorite is a polymict eucrite, and resembles other polymict eucrites collected at the Allan Hills.

Sample No.:

ALHA81007

Location: Allan Hills

Location: Allan Hills

Field No.: Weight (gms):

1553 163.5

Meteorite Type:

Polymict Eucrite

Physical Description: Roberta Score

This achondrite looks typical of the Allan Hills polymict eucrites. These include ALHA76005, A77302, A78040, A78132, A78156, A78165, A80102, A81006, A81007, A81008, A81010.

Dimensions: $8.5 \times 6 \times 2.5 \text{ cm}$.

Petrographic Description: Brian Mason

This specimen is very similar to ALHA81006 in texture and in mineral compositions, and may be tentatively paired with that meteorite. Microprobe analyses show a comparable range in mineral compositions: pyroxene, Wo 3-28, En 31-52, Fs 38-55; plagioclase, An 74-93, mean An 88. The meteorite is classified as a polymict eucrite.

ALHA81008

Location: Allan Hills

Field No.:

1270

Weight (gms):

43.8

Meteorite Type:

Polymict Eucrite

Physical Description: Roberta Score

ALHA81008 is typical of the Allan Hills polymict eucrites.

Dimensions: $5 \times 3.5 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

This specimen is very similar to ALHA81006 and 81007 in texture and in mineral compositions, and can be tentatively paired with those meteorites. Microprobe analyses show a comparable range in mineral compositions: pyroxene, Wo 2-20, En 35-61, Fs 32-59; plagioclase An 80-93, mean An 87. The meteorite is classified as a polymict eucrite.

Sample No.:

ALHA81009

Location: Allan Hills

Field No.:

1500

Weight (gms):

229.0

Meteorite Type:

Eucrite

Physical Description: Roberta Score

ALHA81009 is completely covered with flow marked black fusion crust.

Contained in the light-gray matrix are numerous clasts which are as large as .5 cm in diameter. Oxidation haloes are present.

Dimensions: $7 \times 5.5 \times 3.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section consists largely of brown grains of pigeonite up to 1 mm and colorless grains of plagioclase up to 2 mm in a comminuted groundmass of these minerals. Some lithic clasts, up to 3 mm across, are present; most are fine-grained, but a few have coarse gabbroic textures. No evidence of weathering is visible. Microprobe analyses show pyroxene compositions ranging fairly continuously from Wo $_4^{\rm En}_{33}^{\rm Fs}_{63}$ to Wo $_4^{\rm En}_{26}^{\rm Fs}_{30}$; En content shows a limited range (28-37) except for one grain Wo $_6^{\rm En}_{47}^{\rm Fs}_{47}^{\rm Fs}_{47}^{\rm Fs}$. Plagioclase composition range is An 75-93, mean An 86. The meteorite is a eucrite, but it differs from previously described polymict eucrites from the Allan Hills in the range and distribution of pyroxene compositions.

ALHA81010

Field No.:

1673 219.1

Weight (gms): Meteorite Type:

Polymict Eucrite

Physical Description: Roberta Score

Fusion crust totally covers ALHA81010. This achondrite is probably from the same fall as the other polymict eucrites found in Allan Hills area.

Dimensions: $8 \times 5 \times 5.5 \text{ cm}$.

Petrographic Description: Brian Mason

The meteorite is a microbreccia consisting largely of angular monomineralic pyroxene and plagioclase clasts up to 4 mm in maximum dimension, and a few lithic clasts, in a matrix of comminuted pyroxene and plagioclase. Transparent brown fusion crust rims part of the section. The pyroxene is light to dark brown pigeonite; a few grains show exsolution lamellae. The lithic clasts have a maximum dimension of 3 mm, and consist of pigeonite and plagioclase with ophitic and gabbroic textures; one clast consists of angular pigeonite and plagioclase grains in a semi-opaque glassy matrix. Microprobe analyses show pigeonite and augite with a wide range of compositions: Wo 5-36, En 26-61, Fs 31-57; plagioclase composition range is An 78-93, mean An 88. The meteorite is classified as a polymict eucrite, and is probably paired with ALHA81006, 81007, and 81008.

Sample No.:

ALHA81011

Location: Allan Hills

Location: Allan Hills

Field No.: Weight (gms):

1435 405.7

Meteorite Type:

Eucritic Breccia (possibly a genomict breccia)

Physical Description: Roberta Score

Rounded with scattered patches of black fusion crust, this breccia is clast rich. Several types of clasts are present-typical eucritic clasts, pinkish-white clasts and massive gray clasts. These clasts range in shape from rounded, to lens-shaped, to rectangular, and many are larger than 1.5 cm long. The exterior matrix has a light gray color while the fresh interior matrix is very fine-grained and black. Several areas of oxidation are visible.

Dimensions: $8 \times 6 \times 5 \text{ cm}$.

Petrographic Description: Brian Mason

The meteorite is a breccia of eucritic clasts up to 10 mm in maximum dimension, the clasts sitting in a minor amount of dark glass filled with comminuted grains of pyroxene and plagioclase. The clasts consist of pyroxene and plagioclase and show a variety of textures—finely granular, subophitic, and gabbroic. Microprobe analyses show pyroxene compositions corresponding to pigeonite and augite and clustering around two mean compositions, Wo₄En₃₆Fs₆₀ and Wo₃₅En₃₂Fs₃₃, with a few intermediate values. Plagioclase has fairly uniform composition, An 87-91, mean An 88. The meteorite is a eucritic breccia; although it appears to be polymict, the uniformity of mineral compositions suggest a considerable degree of equilibration, and it may be a genomict breccia.

ALHA81012

Location: Allan Hills

Field No.:

1490

Weight (gms):

36.6

Meteorite Type:

Eucrite

Physical Description: Roberta Score

Flow marks are present on the shiny black fusion crust which covers 75% of ALHA81012.

Small clasts (<2 mm) are abundant in the light gray interior matrix. A few areas have oxidized to an orangish-brown color.

Dimensions: $5 \times 2 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

The section consists largely of brown grains of pigeonite up to 0.9 mm and colorless grains of plagioclase up to 0.6 mm in a comminuted groundmass of these minerals. A few lithic clasts, up to 2.5 mm across, are present; most show ophitic textures. Fusion crust is present along one edge. Microprobe analyses show pyroxene compositions ranging fairly continuously from $Wo_3En_{35}Fs_{62}$ to $Wo_3SEn_{32}Fs_{33}$; En content shows a limited range (30-40) except for one grain $Wo_8En_{48}Fs_{44}$. Plagioclase composition range is An 84-94, mean An 89. The meteorite is a eucrite, but it differs from previously described eucrites from the Allan Hills in the range and distribution of pyroxene compositions. It resembles ALHA81009 closely and is tentatively paired with that meteorite.

ALHA81013

Location: Allan Hills

Field No.:

1645 17727.0

Weight (gms): Meteorite Type:

Hexahedrite

Physical Description: Roy S. Clarke, Jr.

The highly distinctive external appearance of this specimen suggests that it is a fragment that separated during atmospheric break up from a larger mass with cubic cleavage. Its shape is that of a cube that has been shortened along one axis by severe and irregular ablation-sculpturing of a face. This face is the only one that is deeply sculptured with thumb-size regmaglypts, giving the impression that it was part of the exterior surface prior to fragmentation. Its opposite face is approximately square, with slightly rounded edges, and appears to have been the leading surface during late stage ablation. All of the surfaces are covered with a thin reddishbrown coating of secondary oxides which are somewhat thicker within the deeper depressions of regmaglypts. Thin cracks several centimeters long are present on all surfaces and tend to parallel the cubic axes of the specimen.

Dimensions: 16 x 16 x 11 cm.

Tentative Classification: Roy S. Clarke, Jr.

A median slice was removed perpendicular to the square section of the specimen and parallel to opposite sides. One side of the slice was polished and macroetched, resulting in an area of approximately 140 cm available for examination at low magnification. The matrix appears to be single crystal kamacite that etches to a dull finish, atypical for hexahedrites. Several small troilite-daubreelite inclusions are present, as are a few small schreibersites. Slight variations in kamacite reflectivity appear to be due to tiny schreibersites that are unresolvable at low magnification. The most prominent surface feature is the system of orthogonal cracks mentioned above. They penetrate into the interior of the specimen. Neumann bands are absent. This cursory examination suggests that the meteorite is a hexahedrite of somewhat unusual metallography. It probably represents a separate fall, distinct from the typical hexahedrite ALHA78100.

Weight (gms):
Meteorite Type:

Fine Octahedrite

Physical Description: Roy S. Clarke, Jr.

This specimen is an irregularly shaped individual somewhat resembling a fish. It is covered with a uniformly pitted, dark reddish brown, iridescent, secondary iron oxide coating.

Dimensions: $6.5 \times 3 \times 2 \text{ cm}$.

Tentative Classification: Roy S. Clarke, Jr. A microetched surface area of approximately 4.5 cm was examined. section was taken perpendicular to the long axis of the specimen near the more massive end. The edge of the section contains an intermittent thin border of oxide. Below this is a heat-altered zone up to 1 mm thick that is present, with the exception of a few small gaps, around the complete section. Remnant fusion crust was not observed. Kamacite has a rather uniform matte surface at low magnification that can be resolved with higher magnification to a fine epsilon-decomposition structure. A system of wider than average kamacite lamellae, containing frequent centered schreibersites in the 100×200 micron size range, is a prominent feature. Kamacite lamellae free of centered schreibersites have widths in the 0.3 mm range. Plessite fields occupy approximately two-thirds of the surface. Interiors of larger fields contain cellular plessite framed in martensite with taenite borders. Narrow plessite fields have only martensitic areas with taenite borders. Schreibersite is also occasionally present at taenite borders, and as grain boundary schreibersite bridging between adjoining plessite areas. Occasional 5 to 10 micron schreibersites are present within plessite fields. Other inclusions were not observed. The specimen is a fine octahedrite with structural similarities to the high phosphorus IVA meteorite Chinautla. It appears, however, to be even richer in phosphorus and to be distinct from ALHA78252. Chemical data will be required for definitive classification.

Sample No.: ALHA81015 Location: Allan Hills

Field No.: 1652 Weight (gms): 5489.0

Meteorite Type: H5 Chondrite

Physical Description: Carol Schwarz

Thin fusion crust is black to brown and covers about 70% of the specimen. White deposit occurs on one face.

The interior has a partial weathering rind of up to ~ 1 cm in width. Oxidation haloes are numerous in the matrix.

Dimensions: $20 \times 15 \times 9.5 \text{ cm}$.

Petrographic Description: Brian Mason

Chondritic structure is well developed, with chondrules up to 1.2 mm across, but chondrule margins tend to merge with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Veinlets of brown limonite are present near the surface, and limonitic staining is extensive around metal grains. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₆. The meteorite is classified as an H5 chondrite.

Sample No.: ALHA81016 Location: Allan Hills

Field No.: 1635 Weight (gms): 3850.2

Meteorite Type: L6 Chondrite

Physical Description: Carol Schwarz

This specimen has a thin, patchy, remnant fusion crust. Most of the sample is smooth and has weathered to a dark reddish-brown color. Distinct chondrules up to ~ 4 mm in diameter are visible as well as some large mineral grains. A small amount of white deposit has formed along the hairline fractures.

The interior is a lighter brown-green color. No chondrules are distinguishable. However, a large (~ 4 mm) mineral grain with distinct cleavage faces was exposed.

Dimensions: 15 x 12 x 11 cm.

Petrographic Description: Brian Mason

Chondrules are sparse and poorly defined, merging with the granular ground-mass, which consists largely of olivine and pyroxene, with minor amounts of plagioclase, nickel-iron, and troilite, and accessory chromite. A moderate amount of brown limonitic staining is present along grain boundaries. Microprobe analyses give the following compositions: olivine, Fa25; orthopyroxene, Fs21; plagioclase, An11. The meteorite is an L6 chondrite.

ALHA81017

Field No.:
Weight (gms):

1494 1434.4

Meteorite Type:

L5 Chondrite

Physical Description: Carol Schwarz

This specimen consists of two pieces that cannot be fit together, but are obviously the same stone. Each piece has several small patches of dark fusion crust. The samples have a rough texture and are reddish-brown. The matrix is gray with small white and gray inclusions or chondrules. A gray weathering rind was exposed where chips were broken off. Oxidation haloes are also present.

Location: Allan Hills

Location: Allan Hills

Dimensions: $13.5 \times 8 \times 7$ cm and $10 \times 9 \times 5.5$ cm.

Petrographic Description: Brian Mason

Chrondrules are moderately abundant, ranging up to 1.8 mm across, but their margins tend to merge with the granular groundmass, which consists largely of olivine and pyroxene, with minor amounts of nickel-iron and troilite. Microprobe analyses give the following compositions: olivine, Fa₂₅; orthopyroxene, Fs₂₁; one grain of diopside, Wo₄₁Fs₈, was noted. The meteorite is classified as an L5 chondrite.

Sample No.:

ALHA81018

Field No.: Weight (gms):

1421 2236.9

Meteorite Type:

L5 Chondrite

Physical Description: Roberta Score

ALHA81018, an angular shaped stone, is entirely covered with dull black fusion crust. Several cracks penetrate the stone.

The chip obtained for thin section has an approximately one centimeter thick continuous weathering rind. The center of the area exposed is light gray in color with several darker gray colored rounded inclusions.

Dimensions: $13.5 \times 11 \times 10 \text{ cm}$.

Petrographic Description: Brian Mason

This section closely resembles that of ALHA81017, which suggests that these two specimens may be paired. Microprobe analyses give the following compositions: olivine, Fa₂₄; orthopyroxene, Fs₂₁; a little diopside Wo₄₂Fs₉, is present. The meteorite is classified as an L5 chondrite.

Sample No.: ALHA81019 Location: Allan Hills

Field No.: 1428
Weight (gms): 1051.2

Meteorite Type: H5 Chondrite

Physical Description: Carol Schwarz

This specimen is rectangular shaped with thin patchy black fusion crust covering about 65% of its surface. Where the fusion crust is absent the surface is smooth and reddish-brown in color with no features distinguishable. There is a deep fracture penetrating the stone, dividing it into two halves. A small amount of white deposit has formed on the top surface.

The interior is dark reddish-brown with several small areas which are not completely weathered.

Dimensions: $9 \times 7 \times 6.5 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are present but are poorly defined, their margins merging with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Patchy brown limonitic staining is present throughout the section. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₆. The meteorite is classified as an H5 chondrite.

Sample No.: ALHA81020 Location: Allan Hills

Field No.: 1492 Weight (gms): 1352.5

Meteorite Type: H5 Chondrite

Physical Description: Carol Schwarz

ALHA81020 is almost totally covered by a thin, black, polygonally fractured fusion crust. White deposits have formed on one surface.

The interior is light gray in color with numerous oxidation haloes. Some fresh metal is obvious. Small white clasts, 1-2 mm, occur in the matrix.

Dimensions: $11 \times 8 \times 7 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are present, ranging up to 2.2 mm across, but most of the section shows a granular aggregate of olivine and pyroxene with minor amounts of nickel-iron and troilite. Weathering is moderate, being limited to brown limonitic staining around metal grains. A little fusion crust is present on one edge. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₆. The meteorite is classified as an H5 chondrite.

ALHA81021

Field No.:

1424

Weight (gms):

695.1

Meteorite Type:

E6 Chondrite

Physical Description: Carol Schwarz

Flow lines mark the broad top surface of this otherwise smooth and flat specimen. The bottom surface has weathered more extensively than the top.

The interior that was exposed is extremely weathered.

Dimensions: $12 \times 9 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

Only traces of chondritic structure are visible in the section, which consists largely of granular enstatite, with considerable nickel-iron ($\sim 20\%$), minor troilite and plagioclase, and accessory sinoite (Si $_2$ N $_2$ O, identified by its high birefringence). Weathering is extensive, with brown limonitic staining throughout the section. Remnants of fusion crust are present. Microprobe analyses show the enstatite is almost pure MgSiO, (CaO 0.8%, FeO 0.2%, Al₂0₃ 0.2%); plagioclase is An₁₅0r₄; the metal contains about 2% Si. The meteorite is an E6 chondrite

Sample No.:

ALHA81022

Location: Allan Hills

Location: Allan Hills

Field No.: Weight (gms): 1482 912.5

Meteorite Type:

H4 Chondrite

Physical Description: Roberta Score

The bottom surface shows relief with many chondrules apparent. All other surfaces are covered with a thin dull black fusion crust.

This stone was extremely hard to chip. The small piece that fell off revealed an evenly weathered interior with several inclusions visible.

Dimensions: $11.5 \times 10 \times 5.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows a close-packed aggregate of chondrules and chondrule fragments, up to 2.5 mm across, with interstitial fine-grained matrix. wide variety of chondrule types is present, the commonest being porphyritic olivine, granular olivine and olivine-pyroxene, barred olivine, and finegrained radiating pyroxene. Some intergranular glass within the chondrules is pale brown and transparent, but is usually turbid and partly devitrified. Much of the pyroxene is polysynthetically twinned clinobronzite. Small areas of brown limonite are concentrated around the margins of the section. Microprobe analyses show olivine (Fa₁₉) and pyroxene (Fs₁₇) of essentially uniform composition (% mean deviation FeO 2-3). The texture is similar to that of type 3 chondrites, but the homogeneous nature of the olivine and pyroxene indicates type 4; the meteorite is classified as an H4 chondrite. It closely resembles ALHA78084 (recently reclassified from H3 to H4), with which it is tentatively paired.

ALHA81023 Location: Allan Hills

Field No.:

1427

Weight (gms):

418.3

Meteorite Type:

L5 Chondrite

Physical Description: Roberta Score

ALHA81023 was found on the ice in Antarctica as 2 large pieces, 2 small pieces and many tiny chips. None of the pieces fit together, but are obviously related.

The matrix is light gray with many dark colored chondrules, irregular shaped inclusions and troilite(?) grains that show relief from the exterior surface. Some fusion crust is present on each piece. Weathering is moderate. A minute amount of white deposit is present on one piece.

Petrographic Description: Brian Mason

Chondrules are abundant and well developed, ranging up to 2.3 mm across; a variety of types is present, including porphyritic olivine, granular olivine and olivine-pyroxene, and radiating pyroxene. They are set in a granular groundmass consisting largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Weathering is limited to brown limonitic staining around metal grains. Microprobe analyses give the following compositions: olivine, Fa₂₅; orthopyroxene, Fs₂₁. The meteorite is classified as an L5 chondrite; it is very similar to ALHA81017, 81018, and the possibility of pairing with these meteorites should be considered.

Sample No.:

ALHA81024

Field No.:

1510 797.7

Weight (gms): Meteorite Type:

L3 Chondrite

Physical Description: Carol Schwarz

This angular specimen is covered by black blistery fusion crust; some areas are reddish-brown. Several deep fractures penetrate the specimen.

Location: Allan Hills

The interior exposed in chipping is reddish-brown and appears to be extremely weathered.

Dimensions: $10 \times 8 \times 6.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows a close-packed aggregate of chondrules, up to 1.5 mm across; a variety of types is present, including porphyritic olivine, barred olivine, granular olivine and olivine-pyroxene, and fine-grained pyroxene. Much of the pyroxene is polysynthetically twinned clinobronzite. Some intergranular glass within the chondrules is pale brown and transparent, but commonly is turbid and partly devitrified. Minor amounts of nickel-iron (largely altered to brown limonite) and troilite are present in the matrix. Olivine and pyroxene have variable composition. Olivine composition ranges from Fa₃ to Fa₂₈, with a mean of Fa₁₉ (% mean deviation FeO is 34). Pyroxene composition ranges from Fs₂ to Fs₂₄, with a mean of Fs₁₀ (% mean deviation FeO is 79). Transparent chondrule glass has the following mean composition (weight per cent): SiO₂ 63.3, Al₂O₃ 22.5, FeO 0.9, MgO 0.2, CaO 0.2, K₂O 3.3, Na₂O 8.8, TiO₂ 0.8, MnO 0.03; this composition is close to anorthoclase. The texture and the variable mineral compositions are that of type 3, and the amount of metal suggests L group, hence the meteorite is tentatively classified L3. It is possibly paired with ALHA77011 and many other L3 chondrites from the Allan Hills.

Sample No.: ALHA81025 Location: Allan Hills

Field No.: 1598 Weight (gms): 379.0

Meteorite Type: LL3 Chondrite

Physical Description: Roberta Score

Although ALHA81025 is extremely weathered, many clasts, both rounded and irregular, are apparent on the exterior. One notable exterior clast is 7 x 5 mm in diameter. The bottom surface is iridescent brown and covered with squall-like marks. The interior is extensively weathered.

Dimensions: $9.5 \times 8 \times 4.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows a close-packed aggregate of chondrules and chondrule fragments up to 3.5 mm across; in a fine-grained matrix of olivine, pyroxene, troilite, and a little nickel-iron. Chondrule types include porphyritic olivine, granular olivine and olivine-pyroxene, barred olivine, and radiating pyroxene. Much of the pyroxene is polysynthetically twinned clinobronzite. Intergranular glass is present in the chondrules, usually turbid but sometimes transparent and purple-brown. Weathering is extensive, with small areas of brown limonite throughout the section. Microprobe analyses show that olivine and pyroxene have variable composition. Olivine composition ranges from Fa_1 to Fa_{41} , with a mean of Fa_{18} (per cent mean deviation FeO is 76). Pyroxene composition ranges from Fs_3 to Fs_{40} , with a mean of Fs₁₅ (per cent mean deviation FeO is 75). Purple glass in a chondrule has the following mean composition (weight per cent): SiO, 56.8, $A1_{2}0_{3}$ 24.1, FeO 3.7, MgO 2.4, CaO 0.4, $K_{2}0$ 4.1, $Na_{2}0$ 8.8, TiO_{2} 1.2, MnO 0.09. The texture and the variable mineral compositions indicate type 3, and the low metal content suggests LL group, hence the meteorite is tentatively classified LL3. It is possibly paired with ALHA79003 (Scott et al., Meteoritics, 17, 65-75, 1982), 81030, 81031, and 81032.

Sample No.: ALHA81026 Location: Allan Hills

Field No.: 1149 Weight (gms): 515.5

Meteorite Type: L6 Chondrite

Physical Description: Roberta Score

Dull black fusion crust covers some of this knobby-looking equilibrated chondrite.

The interior, exposed by chipping, appears fresh with some haloes around the metal grains.

Dimensions: $11 \times 5.5 \times 6 \text{ cm}$.

Petrographic Description: Brian Mason

Chrondrules are sparse, with diffuse boundaries that merge with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of plagioclase, nickel-iron, and troilite. Weathering is restricted to minor brown limonitic staining around metal grains. Microprobe analyses gave the following compositions: olivine, Fa₂₅; orthopyroxene, Fs₂₁; plagioclase, An₁₀; a grain of apatite was analyzed. The meteorite is an L6 chondrite.

Sample No.: ALHA81027 Location: Allan Hills

Field No.: 1556, 1557 Weight (gms): 3835.3

Meteorite Type: Shocked L6 Chondrite

Physical Description: Roberta Score

ALHA81027 consists of two pieces that fit together perfectly but do not form a complete specimen. Patchy fusion crust covers most of the meteorite. The broken surfaces are smooth and reddish-brown.

The interior of the smaller of the two pieces is totally weathered.

Dimensions: $17 \times 11.5 \times 10 \text{ cm}$

Petrographic Description: Brian Mason

Chondrules are barely discernable, merging with the granular groundmass, which consists largely of olivine and pyroxene, with minor amounts of maskelynite, nickel-iron, and troilite. Remnants of fusion crust rim part of the section. Minor weathering is indicated by brown limonitic staining around metal grains. Microprobe analyses give the following compositions: olivine, Fa₂₅; orthopyroxene, Fs₂₁; maskelynite has CaO content equivalent to An₁₀ but Na₂O is low and variable, 4.0-5.2%. The meteorite is a shocked L6 chondrite.

ALHA81030

Field No.:

1685

Weight (gms):

1851.6

Meteorite Type:

LL3 Chondrite

Physical Description: Roberta Score

This angular stone is covered with patchy black fusion crust. Several large fractures penetrate the interior. A few inclusions are visible on the exterior. The bottom contains squall-like marks.

Chipping exposed an interior of dark gray matrix material with small inclusions visible.

Dimensions: $18 \times 7.5 \times 9 \text{ cm}$.

Petrographic Description: Brian Mason

This specimen closely resembles ALHA81025 in texture, range of mineral compositions, and degree of weathering. It is therefore classified as an LL3 chondrite and tentatively paired with that meteorite.

Sample No.:

ALHA81031

Location: Allan Hills

Location: Allan Hills

1675 1594.9

Weight (gms): Meteorite Type:

LL3 Chondrite

Physical Description: Carol Schwarz

This angular specimen has only small patches of fusion crust remaining on its weathered surface. Many large fractures penetrate the stone. A piece fell off in handling to reveal a totally weathered interior.

Dimensions: $13 \times 9 \times 9 \text{ cm}$.

Petrographic Description: Brian Mason

This specimen closely resembles ALHA81025 in texture, range of mineral compositions, and degree of weathering. It is therefore classified as an LL3 chondrite and tentatively paired with that meteorite.

Sample No.: ALHA81032 Location: Allan Hills

Field No.: 1686 Weight (gms): 726.8

Meteorite Type: LL3 Chondrite

Physical Description: Carol Schwarz

This angular specimen has thin patchy fusion crust. Where devoid of fusion crust clasts or chondrules up to 0.5 cm are visible in the weathered matrix.

Chipping revealed no fresh material.

Dimensions: $9 \times 9 \times 6 \text{ cm}$.

Petrographic Description: Brian Mason

This specimen closely resembles ALHA81025 in texture, range of mineral compositions, and degree of weathering. The mean compositions of olivine (Fa_{15}) and pyroxene (Fs_{11}) are somewhat lower, but this is probably due to the inclusion of several grains of almost iron-free forsterite and enstatite. It is therefore classified as an LL3 chondrite and tentatively paired with that meteorite.

Sample No.: ALHA81033 Location: Allan Hills

Field No.: 1318 Weight (gms): 252.4

Meteorite Type: H5 Chondrite

Physical Description: Carol Schwarz

This sample consists of six similar fragments. They have only small areas of remnant fusion crust and are mostly weathered. One of the smaller pieces was selected for thin section.

Dimensions: $7 \times 4.5 \times 3 \text{ cm}$ (largest piece)

Petrographic Description: Brian Mason

Chondritic structure is well developed, but the chondrules tend to merge with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Weathering is extensive, with brown limonitic staining and small areas of limonite throughout the section. Microprobe analyses give the following compositions: olivine, Fa₁₈; orthopyroxene, Fs₁₆. The meteorite is classified as an H5 chondrite.

H5 Chondrite

Physical Description: Roberta Score

Black fusion crust covers 50% of this meteorite. Several regmaglypts are present on one surface. The broken surfaces have weathered to a deep reddish-brown color.

Location: Allan Hills

Location: Allan Hills

Chipping revealed an interior that is uniformly mottled with oxidation. Inclusions are obvious.

Dimensions: $7 \times 6 \times 4 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are fairly abundant but are poorly defined, tending to merge with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Limonite veinlets and brown limonitic staining are present throughout the section. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₇. The meteorite is classified as an H5 chondrite.

Sample No.:

ALHA81035

Field No.:

1562

Weight (gms):

256.1

Meteorite Type:

H6 Chondrite

Physical Description: Roberta Score

This is a complete specimen with patchy fusion crust covering the entire meteorite. Only weathered material was exposed when ALHA81035 was chipped.

Dimensions: $7.5 \times 5.5 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are relatively sparse and poorly defined; most of the section is a granular aggregate of olivine and pyroxene, with minor amounts of nickeliron, troilite, and plagioclase. Weathering is extensive, with limonite veinlets and small areas of limonite throughout the section. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₇; plagioclase, An₁₃. The meteorite is classified as an H6 chondrite.

ALHA81036

Location: Allan Hills

Field No.:

1633

Weight (gms):

252.1

Meteorite Type:

H5 Chondrité

Physical Description: Carol Schwarz

This specimen has thin (<1 mm) black fusion crust that is slightly weathered in some areas. Regmaglypts occur on several faces. The interior is totally weathered.

Dimensions: $7 \times 4.5 \times 4.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section consists largely of a granular aggregates of olivine and pyroxene, with relatively few chondrules; nickel-iron and troilite are present in minor amounts. Remnants of fusion crust rim the section. Brown limonitic staining and limonite veinlets are present. Microprobe analyses give the following compositions: olivine, Fa19; orthopyroxene, Fs17. meteorite is classified as an H5 chondrite.

Sample No.:

ALHA81037

Location: Allan Hills

Field No.:

1489

Weight (gms):

320.3

Meteorite Type:

H6 Chondrite

Physical Description: Carol Schwarz

This angular specimen has fusion crust on all but two sides. The fusion crust is black with rust haloes and is polygonally fractured.

The interior is moderately weathered with oxidation haloes in a light yellowish-gray matrix.

Dimensions: $7.5 \times 6 \times 4 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are sparse and poorly defined, merging with the granular groundmass, which consists largely of olivine and pyroxene, with minor amounts of nickel-iron, troilite, and plagioclase. Well preserved fusion crust is present along one edge. Areas of brown limonitic staining occur throughout the section. Microprobe analyses give the following compositions: olivine, Fa20; orthopyroxene, Fs17; plagioclase, An12. The meteorite is an H6 chondrite.

ALHA81038

Field No.:

1578

Weight (gms):

229.0

Meteorite Type:

H6 Chondrite

Physical Description: Roberta Score

Several millimeter-sized patches of fusion crust remain on the exterior of this weathered meteorite. There are several fractures which penetrate the interior.

Location: Allan Hills

Location: Allan Hills

Chipping exposed only weathered material.

Dimensions: $7 \times 4 \times 4 \text{ cm}$.

Petrographic Description: Brian Mason

This section appears to be identical in texture, mineral compositions, and degree of weathering with that of ALHA81035, and is therefore paired with that meteorite. It is an H6 chondrite.

Sample No.:

ALHA81039

Field No.:

1495

Weight (gms):

205.9

Meteorite Type:

H5 Chondrite

Physical Description: Carol Schwarz

This specimen conists of two pieces which fit together plus a small (\sim 1.5 cm) piece. The two larger pieces have black pitted fusion crust on all sides but one. The small piece is nearly totally covered with fusion crust.

Chipping revealed a light gray matrix with oxidation haloes. A weathering rind has formed along the face where fusion cust is absent.

Dimensions: $10 \times 4.5 \times 4 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are present, but are poorly defined, their margins tending to merge with the granular groundmass, which consists largely of olivine and pyroxene, with minor amounts of nickel-iron and troilite. Minor weathering is indicated by brown limonitic staining concentrated around metal grains. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₇. The meteorite is classified as an H5 chondrite.

ALHA81040

Field No.:

1571

Weight (gms):

194.5

Meteorite Type:

L4 Chondrite

Physical Description: Roberta Score

Dull black fusion crust covers approximately 3/4 of this rounded stone. Areas with no fusion crust have weathered to a deep reddish-brown. A small interior area of mostly weathered material with very dark matrix and some metal flecks was revealed by chipping.

Location: Allan Hills

Location: Allan Hills

Dimensions: $5.5 \times 5 \times 5 \times 5$

Petrographic Description: Brian Mason

The section shows numerous well-defined chondrules in a granular groundmass consisting largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Chondrule types include porphyritic olivine and olivine-pyroxene, and fine-grained radiating pyroxenes. Much of the pyroxene is polysynthetically twinned clinobronzite. Brown limonitic staining is extensive throughout the section. Microprobe analyses give the following compositions: olivine, Fa₂₅; pyroxene, Fs₂₁. The meteorite is classified as an L4 chondrite.

ALHA81042

1640

Field No.: Weight (gms):

534.4

Meteorite Type:

H5 Chondrite

Physical Description: Carol Schwarz

This specimen has patchy fusion crust on its shiny red-brown exterior. It is extensively fractured. The interior appears to be totally weathered.

Dimensions: $10 \times 7 \times 5 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are fairly abundant, but their margins are diffuse, tending to merge with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of nickel-iron and troilite. Weathering is extensive, with brown limonitic staining and veinlets throughout the section. Microprobe analyses give the following compositions: olivine, Fa19; orthopyroxene, Fs17. The meteorite is classified as an H5 chondrite.

ALHA81044

Field No.:

1125

Weight (gms):

386.8

Meteorite Type:

H4 Chondrite

Physical Description: Carol Schwarz

This meteorite is extremely weathered and fractured. No fresh material was exposed by chipping.

Dimensions: $8.5 \times 6 \times 5 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are abundant, and are set in a granular groundmass of olivine and pyroxene, with minor amounts of nickel-iron and troilite. Some of the pyroxene in chondrules is polysynthetically twinned clinobronzite. Brown limonitic staining pervades the section. Microprobe analyses give the following compositions: olivine, Fa₁₈; pyroxene, Fs₁₆. The meteorite is classified as an H4 chondrite.

Sample No.:

ALHA81048

Location: Allan Hills

Location: Allan Hills

Field No.: Weight (gms):

1121 190.6

Meteorite Type:

H4 Chondrite

Physical Description: Carol Schwarz

This specimen has no fusion crust except for a small amount of remnant crust on one face. It is extremely weathered and fractured. Chipping exposed a thick weathering rind and only small areas of less weathered material.

Dimensions: $8.5 \times 4.5 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

This section is essentially identical with that of ALHA81044 in texture, mineral compositions, and degree of weathering. It is classified as an H4 chondrite and tentatively paired with that meteorite.

Sample No.: ALHA81059 Location: Allan Hills

Field No.: 1282 Weight (gms): 539.5

Meteorite Type: Mesosiderite

Physical Description: Roberta Score

The exterior of this mesosiderite has many greenish pyroxene grains, which all show cleavage faces. Several of the larger ones (up to 1.5 x 1 cm) can easily be removed. The stone appears to be fairly weathered with many fractures criss-crossing the exterior. A few small patches of fusion crust remain.

Weathering of the interior is extensive.

Dimensions: $9.5 \times 5 \times 5.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section consists largely of orthopyroxene clasts ranging up to 10 mm in maximum dimensions, together with about 30% of nickel-iron in grains up to 0.6 mm; a little troilite is present. The meteorite is extremely weathered and seamed with brown limonite. Microprobe analyses shows that the orthopyroxene is somewhat variable in composition, ranging from Fs₂₅ to Fs₃₂, with a mean of Fs₂₈; mean weight per cent CaO is 1.2, MnO 0.7, Al₂O₃ 0.6, TiO₂ 0.2. Small amounts of olivine (Fa₂₈), plagioclase (An₉₃), merrillite, and an SiO₂ phase (probably tridymite) were detected with the microprobe. The meteorite is a mesosiderite, the second from the Allan Hills. It appears to be different from the previous one, ALHA77219.

Sample No.: ALHA81067 Location: Allan Hills

Field No.: 1597, 1599 Weight (gms): 227.6

Meteorite Type: H5 Chondrite

Physical Description: Carol Schwarz

This specimen consists of two pieces which fit together perfectly. The "exterior" surfaces have a thin patchy fusion crust while the "interior" surfaces are a dark iridescent brown. The interior exposed by chipping is totally weathered.

Dimensions: $7 \times 5.5 \times 4 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are abundant, but for many of them their margins are diffuse, merging with the granular groundmass, which consists of olivine and pyroxene with minor amounts of nickel-iron and troilite. Weathering is extensive, with limonite veinlets throughout the section. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₇. The meteorite is classified as an H5 chondrite.

ALHA81093

Field No.:

1488 271.0

Weight (gms):

Meteorite Type:

H6 Chondrite

Physical Description: Roberta Score

Dull black fusion crust totally covers this meteorite. The interior has a discontinuous weathering rind with oxidation evenly distributed throughout. Small light and dark inclusions are visible in the gray-white matrix.

Dimensions: $6 \times 5.5 \times 4 \text{ cm}$.

Petrographic Description: Brian Mason

Chrondritic structure is barely perceptible, the few chondrules being extensively integrated with the granular groundmass, which consists largely of olivine and pyroxene, with minor amounts of nickel-iron, troilite, and plagioclase. Limonitic staining and small areas of limonite are present throughout the section. Microprobe analyses give the following compositions: olivine, Fa₂₀; orthropyroxene, Fs₁₇; plagioclase, An₁₂. The meteorite is an H6 chondrite.

Sample No.:

ALHA81102

Location: Allan Hills

Location: Allan Hills

Field No.:

1610

Weight (gms):

196.0

Meteorite Type:

H6 Chondrite

Physical Description: Carol Schwarz

The specimen has only a thin remnant fusion crust in patches with most of the surface being a dark red-brown color. A few <1 mm chondrules are visible. The interior exposed in chipping is dark red-brown in color.

Dimensions: $7.5 \times 5 \times 3 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are present, but are extensively integrated with the granular groundmass, which consists largely of olivine and pyroxene with minor amounts of nickel-iron, troilite, and plagioclase. Weathering is extensive, with limonitic staining and small areas of limonite throughout the section. Microprobe analyses give the following compositions: olivine, Fa_{10} ; orthopyroxene, Fs_{17} ; plagioclase, An_{12} . The meteorite is an H6 chôńdrite.

Sample No.: ALHA81111 Location: Allan Hills

Field No.: 1431 Weight (gms): 210.3

Meteorite Type: H6 Chondrite

Physical Description: Roberta Score

The top half of ALHA81111 is covered with frothy black fusion crust while the remainder of the specimen is iridescent reddish-brown. Several cracks penetrate the interior.

Chipping exposed only a small area of relatively unweathered material which is a very dark gray color.

Dimensions: $8 \times 4 \times 6 \text{ cm}$.

Petrographic Description: Brian Mason

Chondrules are moderately abundant but their margins are diffuse, tending to merge with the granular groundmass, which consists of olivine and pyroxene with minor amounts of nickel-iron, troilite, and plagioclase. Limonitic staining and small areas of limonite are present, mainly in association with metal grains. Microprobe analyses give the following compositions: olivine, Fa₁₉; orthopyroxene, Fs₁₇; plagioclase, An₁₃. The meteorite is an H6 chondrite.

Sample No.: ALHA81251 Location: Allan Hills

Field No.: 1248 Weight (gms): 158.0

Meteorite Type: LL3 Chondrite

Physical Description: Roberta Score
Thin, black, shiny fusion crust covers half of this flat sample. The exterior appears to have been polished, and the broken surfaces show

abundant chondrules as large as 0.5 cm in diameter.

The interior exposed by chipping has weathered to a deep reddish-brown, obliterating any structure present.

Dimensions: $6.5 \times 6 \times 2.5 \text{ cm}$.

Petrographic Description: Brian Mason

The section shows a close-packed aggregate of chondrules and chondrule fragments, up to 3 mm in maximum dimension. Most of the matrix is black and opaque, with small grains of olivine and pyroxene; the black matrix appears to be carbonaceous, with small amounts of troilite and nickel-iron (largely weathered to limonite). A wide variety of chondrule types is present, including barred olivine, granular olivine and olivine-pyroxene, and fine-grained pyroxene. Clear glass is present in barred olivine chondrules. Microprobe analyses show olivine and pyroxene with variable compositions: olivine, Fa₁-Fa₂₉, mean Fa₁₄ (per cent mean deviation FeO is 64); pyroxene, Fs₂-Fs₂₈, mean Fs₁₃ (per cent mean deviation FeO is 72). Clear glass in a barred olivine chondrule has the following composition (weight per cent): SiO₂ 61.4, Al₂O₃ 23.5, FeO 1.7, MgO 2.0, CaO 0.4, Na₂O 4.8, K₂O 1.6, TiO₂ 1.1, MnO 0.01. The highly variable composition of olivine and pyroxene and the texture indicate Type 3. The small amount of nickel-iron suggests LL group. Hence the meteorite is tentatively classified as an LL3 chondrite.
