Basaltic or gabbroic fragmental breccia

31, 53 g

EET87521

Figure 1A: Photograph of Elephant Moraine (EET) 87521 taken at the Johnson Space Center in the Meteorite Processing Laboratory. Figure 1B: Photograph of EET 96008 taken at the Johnson Space Center in the Meteorite Processing Laboratory.

## Introduction

On the 1987-1988 ANSMET expedition, a 31 g achondrite, EET 87521 (Fig. 1A), was discovered in the Elephant Moraine Icefield (EET), in a sub-region referred to as Meteorite City (Figs. 2 and 3). Initially, EET 87521 was classified as a eucrite, based on its texture and mineralogy. However, after more detailed study including determination of Fe/Mn, Ga/Al and O isotopic ratios, it was recognized as a lunar basaltic breccia and immediately reclassified (Delaney, 1989; Warren and Kallemeyn, 1989; Score and Lindstrom, 1990). This was the first meteorite discovered that was derived from a mare region on the Moon. Nine years later, in the 1996-1997 ANSMET season, another paired and larger (53 g) piece of this breccia was discovered in Meteorite City – EET 96008.

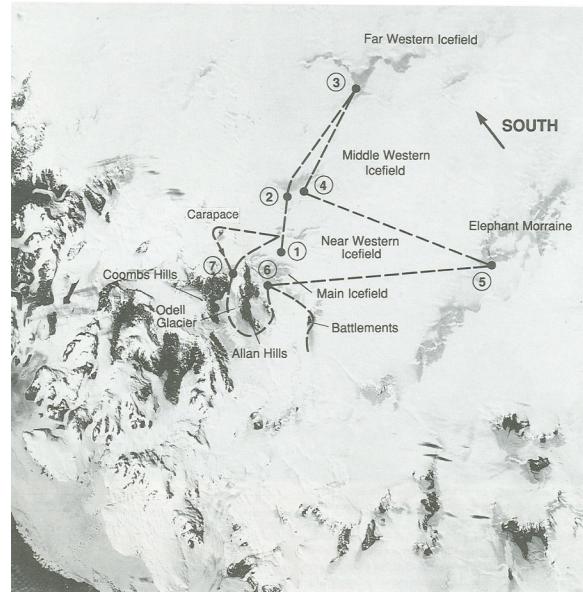

Figure 2: The Elephant Moraine icefield region, home of the EET series ANSMET meteorites.

Figure 3: Meteorite City region of the Elephant Moraine Icefield where EET 87521 and EET 96008 were discovered.

### Petrography and Mineralogy

EET 87521 and EET 96008 are both basaltic regolith breccias that contain a diversity of clasts that have a mare affinity. Takeda et al. (1992) described basaltic, gabbroic and feldspathic basaltic clasts in section ,55. Warren and Klemme (1989) found ophitic basalt clasts as well as some highlands material and impact melts in section ,9. Both Warren and Klemme (1989) and Anand et al. (2003) estimate modes of approximately 80% brecciated matrix and 20% clasts for EET 87521 and EET 96008, respectively. Finally, Delaney (1989) reports 10% olivine, 47% subcalcic pyroxene, 38% calcic plagioclase, 4% silica and 1% of ilmenite, chromite, Ti-chromite and sulfide in section ,8.

Pyroxene compositions are variable and extend to very Fe-rich components (Fig. 6). Although there is plagioclase as sodic as An<sub>70</sub>, the preponderance of feldspar compositions are near An<sub>90-92</sub> (Figure 7). The range of spinel compositions in the EET basaltic

meteorites spans nearly the entire range documented in Apollo lunar mare basalt suites, from Cr-rich spinel to Ti-chromites to ulvöspinel (Fig. 8).

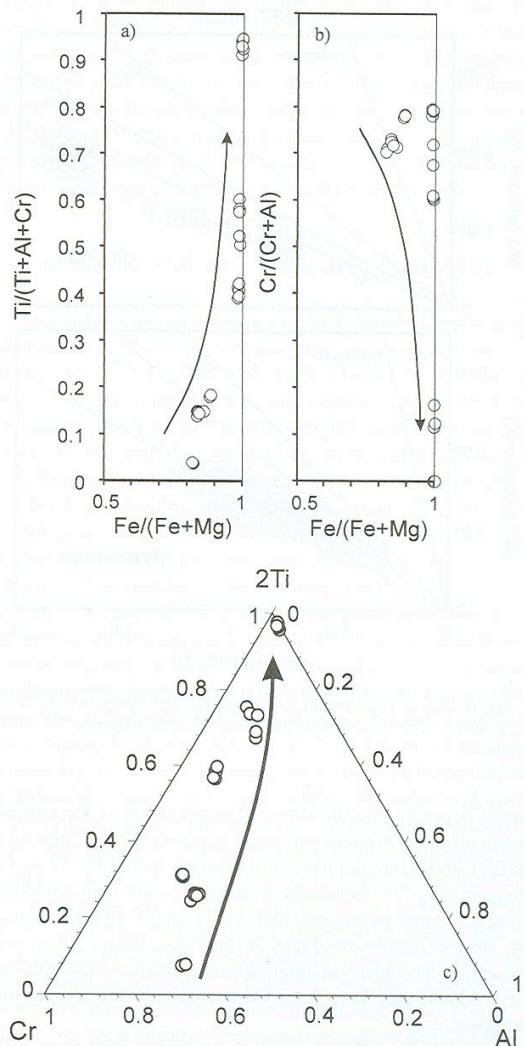

Figure 8: Spinel compositions for EET 96008 (Anand et al., 2003).

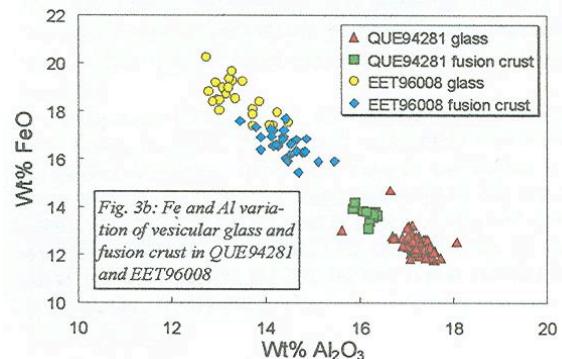

Figure 9: Composition of glass and fusion crust in EET 96008 compared to QUE 94281 (from Mikouchi et al., 2001)

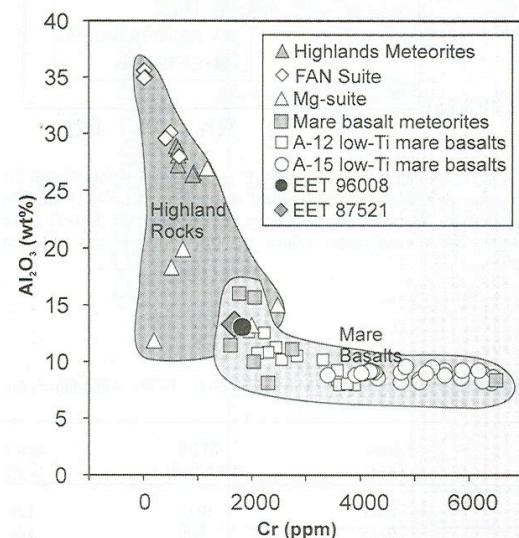

Figure 10: Bulk composition (Cr and  $\text{Al}_2\text{O}_3$ ) for EET 96008 and EET 87521 compared to highland rocks and mare basalts (from Anand et al., 2003).

## Chemistry

Numerous fractions of EET 87521 and EET 96008 have been analyzed by INAA and ICP-MS techniques (Table 1). A plot of  $\text{Al}_2\text{O}_3$  vs. Cr shows that the EET meteorites plot at the intersection of the highlands and mare basalt fields. Their compositions are nearly identical, and very similar to many other lunar mare meteorites (Fig. 10). Analyses of glasses in EET 96008 illustrate their

basaltic nature compared to  $\text{Al}_2\text{O}_3$ -rich and FeO-poor glass analyses from highland breccia QUE 94281 (Fig. 9). Rare earth element data for EET 87521 and 96008 show the similarity to other mare basalts from Apollo and more basalt meteorites, given their distinct negative Eu anomalies, and elevated REE in general compared to highland meteorites (Fig. 11). Siderophile elements in EET 87521 and EET 96008 exhibit large concentration variations, typical of lunar breccias in general, such as Ir (Anand et al., 2003; Warren and Kallemeyn, 1991; Korotev et al., 2003). Variations between sub samples of EET 87521 and EET 96008 can be attributed to the brecciated nature of the sample. Finally, noble gas abundance patterns for the EET meteorites show their similar, but relatively low concentrations of noble gases compared to highlands meteorite DaG 262 and solar noble gas-rich highland meteorite QUE 93069 (Fig. 12).

### Radiogenic age dating

There has been no published Rb-Sr, Lu-Hf or Sm-Nd data for the EET meteorites.

There has been a U-Pb study of apatite and whitlockite from EET 96008, yielding an isochron of 3.69 Ga (Fig. 13), but with sizable error. Similar study of EET 87521 phosphates yielded age of 3.531 Ga, in agreement (within error) of the results for EET 96008 (Fig. 14; Terada et al., 2005).

$^{40}\text{K}$ - $^{40}\text{Ar}$  gas retention ages for all phases in EET 87521 show a 3.30 Ga age (Eugster et al. (1996)). This is in agreement with the results of Fernandes and Burgess (2006) who report a 3.23 Ga age for EET 96008.

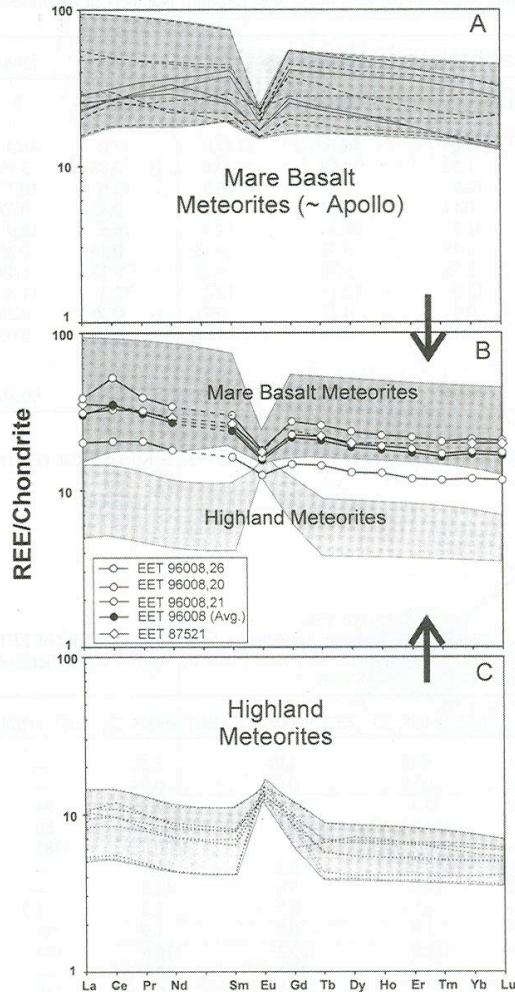

Figure 11: Rare earth element data for EET 87521 and 96008 illustrating the similarity of these meteorites to mare basalt.

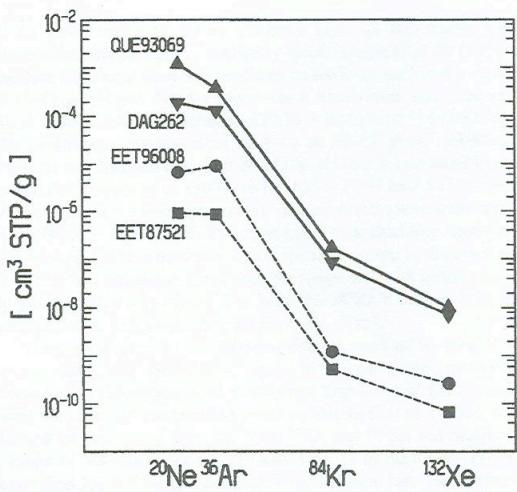

Figure 12: Noble gas data for EET 87521 and EET 96008 compared to two other lunar meteorites: QUE 93069 and DaG 262 (from Polnau and Eugster, 1999).

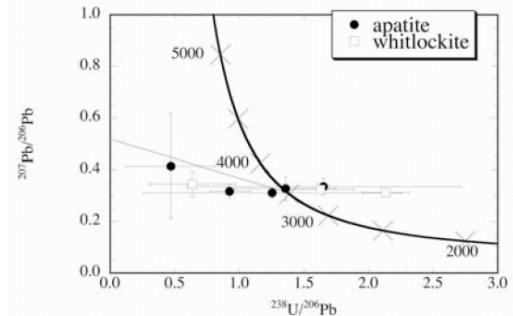

Figure 14: U-Pb data for apatite and whitlockite from EET 87521, illustrating the 3.531 Ga age (from Terada et al., 2005).

### Cosmogenic isotopes and exposure ages

A summary of the ejection, transfer, and terrestrial exposure ages is presented in the introduction to this compendium. Only brief mention of detailed studies will be made here for the sake of brevity. Eugster et al. (2000) propose a three stage history for EET 96008: an early stage, ~500 Ma ago, lasting ~9 Ma at a shallow shielding depth, followed by the second stage when the material was buried (without exposure) until the third stage, where it was buried at an intermediate depth for about 26 Ma until ejection. This history is nearly identical to that proposed for EET 87521, and is solid basis for pairing of these two meteorites. Vogt et al. (1993) and Nishiizumi et al. (1999) demonstrate that the transit time of these meteorites from the Moon to the Earth was much less than 10 Ka, and the terrestrial residence time was 80 +/- 30 Ka.

## **Processing**

EET 87521 was processed in two main stage: initial processing between June 1988 and February 1990, until it was recognized as a lunar meteorite and then between March and August 1990 when it was studied by consortium including C. Schwarz, J.S. Delaney, P. Warren, and M. Lindstrom (Figure 15,16,19). Most allocations to scientists have been from ,0 and ,11 (Table 2). EET 96008 was also processed in two main stages: initial processing in April 1997 and then most allocations in July 1998 (Figure 17, 18, 20). Most of the allocations have been from ,3 and ,0 (Table 3).
